

The Paradox of Profit

Phase 1: The Engagement Reality Check (Foundation)

- **The Business Problem:** We know how our users behave, but we don't know if that behavior is *normal*. Are our users actually engaged, or are they just passively scrolling compared to the rest of the world?
- **The SQL Task:** Join the two tables and calculate the "Engagement Gap" (User Engagement Rate minus the Global Average Engagement Rate) for every single user.

Phase 2: The Addiction-Commerce Nexus (Monetization)

- **The Business Problem:** Companies care about money. Which platforms have the highest global "Social Commerce Adoption," and are those same platforms causing the highest "Addiction Levels" in our specific users?
- **The SQL Task:** Aggregate user addiction levels and average monthly spending by platform, and map it directly against the global social commerce adoption percentage.

Phase 3: The Productivity Drain (Human Cost)

- **The Business Problem:** High screen time equals high ad revenue, but what is the cost? Do platforms with higher global daily time averages cause worse productivity and sleep loss in our users?
- **The SQL Task:** Group users by their productivity_impact and primary_platform, comparing their actual sleep hours and screen time against the platform's global standards.

Phase 4: The "Burnout" Churn Risk (Predictive Value)

- **The Business Problem:** Users who spend a lot of money but report "Negative" mental health are a massive churn risk. They will eventually delete the app. Who are they, and what platforms do they use?
 - **The SQL Task:** Use advanced CASE statements and Window Functions to segment users into risk categories ("High Value/Low Risk", "High Value/High Flight Risk", "Passive").
-
